

E-commerce Website(Thunder)

Week 11 Jyothiswaroop Sreenivasulureddy(02147898)

Access to DB from Short URL

1. The short URLs have unique identifiers linking each user with each having a unique identifier store.
2. The frontend after the user has logged in triggers a GET request which grants access to the URL from the backend API
3. Any time a request is made the server retrieves the identifier, searches the database, and provides the desired output

Decrypt Data and Present to Use

The encryption and decryption of data does happen in two ways;

1. Crypto data is encrypted at storage before being stored in the database.
2. Whenever data is required, it is fetched from the database, decrypted by validating an encryption key, and sent through an API to the frontend

Destroy Data in DB

Through a DELETE request, data is permanently deleted by identifying and verifying it using a unique identifier. The user is assured that data is non-retrievable upon deleting it.

Handle Expiring Data

MongoDB does provide a TTL(Time-To-Live) which is a countdown to how long data is stored. After which the data is deleted. This is useful when it comes to cart items.
